

1. Direct In-Depth Interviews (5 Specific Women) The research includes detailed profiles and direct interview data from five women, highlighting a variety of lived experiences, complications, and backgrounds:

- **Poonam:** A mother from Delhi with a BA education, whose second pregnancy involved severe nausea and extreme smell sensitivities to foods like roti and garlic.
- **Rachna Aunty:** A mother from Noida in her 6th month of her second pregnancy, who experienced nausea for 9 months and heavily prioritizes doctor validation over online advice.
- **Ruchita:** A 30-year-old IT engineer in her first pregnancy who uses AI tools like ChatGPT to simplify complex medical jargon and relies on a professional dietician.
- **Saumya:** A mother who conceived twins via IVF and faced severe, high-risk complications, including 17 days in the ICU, gestational diabetes, and complete bed rest.
- **Achala:** A 29-year-old housewife from a Marathi-medium background in her second pregnancy, who struggles with English medical terms and uses Google to translate information into Marathi.

2. The 10 Synthetic Personas To simulate authentic survey responses across India's diverse socioeconomic, cultural, geographic, and linguistic matrix, the researchers synthesized their primary data into 10 detailed personas. (Notably, the survey data maps several of these personas directly to anonymous Reddit users). These 10 profiles represent the core target users for the platform:

- **Savitri Yadav (19):** A rural user from UP in a joint family with very low digital access, relying entirely on her mother-in-law and local health workers.
- **Rohini Nair (34):** A highly educated software engineer from Kochi managing her postpartum C-section recovery mostly alone while her husband works in Dubai.
- **Parveen Shaikh (23):** A teacher in Bhopal navigating a joint family where she feels pressured to fast during Ramzan against her doctor's advice.
- **Lalita Meena (21):** A tribal agricultural worker from semi-rural Rajasthan with no smartphone and no formal prenatal care at 10 weeks pregnant.
- **Deepika Arora (29):** A homemaker in Indore 10 months postpartum, struggling with the loss of her professional identity.
- **Anita Gogoi (26):** A clerk in Guwahati facing a high-risk Gestational Diabetes diagnosis without any pregnancy resources available in her native Assamese.
- **Reshma Patil (31):** A business owner from Nagpur looking for Marathi-language content and guidance on managing physical work in retail during her pregnancy.
- **Kamla Srinivasan (38):** A highly health-literate executive in New Delhi managing severe anxiety during a high-risk IVF pregnancy.
- **Sundaramma K. (24):** A Tamil-speaking factory worker from Coimbatore forced to return to work just 3 months postpartum due to financial pressure.
- **Preethi Menon (27):** A product analyst in Bengaluru managing moderate anaemia and struggling to find dietary advice suited to her native Andhra food culture.

3. Online Community Data (Reddit Users) The researchers collected qualitative, unstructured data from various Reddit threads discussing first-time parenting. This data captures raw, emotional accounts of the maternal experience, including:

- The profound shock of postpartum physical and emotional changes, including deep dives into postpartum depression and anxiety.
- The realities of severe morning sickness, first-trimester anxiety, and the mental toll of waiting weeks between early sonograms.
- Advice from experienced mothers to first-timers, emphasizing the need to stay off anxiety-inducing social media and to prioritize self-care.

4. Medical and Community Health Workers Beyond mothers, the structured primary research was conducted through observational sessions, surveys, and interviews with key healthcare providers who manage the Indian maternal ecosystem. This included:

- **ANMs (Auxiliary Nurse Midwives) and ASHA workers:** Who act as the primary, and sometimes only, source of health information for rural and low-income mothers.
- **Gynaecologists:** Expert interviews with doctors were used to understand clinical pain points, such as the fact that doctors spend a massive amount of consultation time correcting misinformation patients find on Google or through unverified AI tools
